Abstract

The impact of potentially toxic chemicals on wildlife is commonly assessed by comparing the intake of the contaminant with the “no observable effects level” (NOAEL) of intake. It is known, however, that there are considerable uncertainties inherent in this method. This study presents a Monte-Carlo based model to assess the degree of risk posed to birds (dunlin, *Calidris alpina*) from important estuarine habitats, and to show the limitations of such risk assessments, particularly with regard to data availability. The model was applied to predict the uptake of metals (Hg, Pb) in this shorebird species in Poole Harbour and the Severn Estuary/Bristol Channel, UK, two internationally important shorebird habitats. The results show that in both areas, Pb and Hg concentrations may pose an ecologically-relevant toxic risk to wading birds. For Pb, uncertainty in NOAEL values dominates the overall uncertainty. Use of lethal toxicity data (LD50/100) was investigated as a method for assessing sub-lethal impacts from Hg. It was found that this method led to a significant under-estimate of the potential impact of Hg contamination, compared with direct estimation of NOAEL.

Key words: mercury, lead, probabilistic modelling, estuaries, reproductive toxicity, dunlin.

1 **1. INTRODUCTION**

2

3 Analysis of uncertainty in environmental risk assessments is becoming increasingly important
4 (e.g. Verdonck et al., 2005). To our knowledge, however, modelling approaches have not yet
5 been developed for the assessment of uncertainty in contaminant uptake and risk in wading
6 birds. Here we present a probabilistic modelling approach for risk assessment that employs
7 ecologically relevant toxicological endpoints and, crucially, data inputs (bird behaviour,
8 metal content of prey items, toxicity endpoints) that are realistic for typical environmental
9 impact assessments. The Monte-Carlo based model is used to assess the degree of risk posed
10 to birds from important estuarine habitats, and to show the limitations of such risk
11 assessments, particularly with regard to data availability.

12

13 Estuaries are typically important feeding areas for wading birds but are also often subject to
14 historic and current chemical contamination by heavy metals. Estuarine sediments
15 commonly form major sinks for contaminants released during industrial activity. Many
16 industrial processes lead to the release of metals initially in solution, which can then be
17 adsorbed on to, for example, Fe hydroxides or clay minerals (Pirrie et al., 2003) and are
18 subsequently deposited onto estuarine sediments. Both past mining activity and present
19 industrial discharges have resulted in the accumulation of metals in estuarine sediment.

20

21 The Severn Estuary/Bristol Channel and Poole Harbour (Figure 1) are two major UK
22 estuaries and are classified as Special Protection Areas (SPAs) under the European Wild
23 Birds Directive. During the winter, they support nationally and internationally important
24 numbers of overwintering shorebirds (Pickess and Underhill-Day, 2002; Pollitt et al., 2003).
25 However, both areas are typical of estuaries in that they have previously been subject to
26 significant metal contamination. Much of the metal contamination has been adsorbed onto

27 estuarine sediments and as a consequence concentrations of heavy metals in sediments
28 usually exceed those of the overlying water by between three and five orders of magnitude.
29 With such high concentrations, the bioavailability of even a small fraction of the total
30 sediment metal can lead to uptake by filter-feeding and burrowing organisms (Bryan and
31 Langston, 1992). Furthermore, several metals, including mercury and lead, may be
32 transformed in sediments to organometallic compounds which have greater bioavailability.
33 These factors can result in accumulation of heavy metals by wading birds feeding in these
34 areas (Bryan and Langston, 1992; Ferns and Anderson, 1997). Although there is evidence
35 that metal contamination is declining in both Poole Harbour (Langston, 2003a) and the
36 Severn Estuary (Duquesne et al., 2006; Langston et al., 2003b), the current levels of
37 contamination suggest that they could still potentially have an impact on wildlife.

38

39 Assessment of the potential risk to wading birds posed from contamination has rarely been
40 carried out, except where there have been specific spills or industrial incidents (Bull et al.,
41 1983); (Pain et al., 1998). The aim of the current paper is to use the Severn Estuary and
42 Poole Harbour as model systems (for which relatively good empirical data are available) to
43 assess the potential risk posed to wading birds from long-term metal contamination in
44 estuaries. A Monte Carlo analysis will be carried out to estimate the probability that the
45 wading bird population is over-exposed to Pb and Hg in the two estuaries.

46

47 **METHODS**

48

49 The variability in population-averaged risk to dunlin, *Calidris alpina*, was assessed using a
50 scenario approach. This species was selected because data on its diet selection and habitat
51 use are available for both estuaries. Modelling was carried out in both estuaries for two

52 scenarios: the ‘Average’ Scenario and the ‘Worst Case’ scenario. The ‘Average’ Scenario
53 represents the best estimate and range of possible PPC/PNEC (predicted prey
54 concentration/predicted no effect concentration in prey) values for the average bird, which is
55 assumed (over a season) to have a dietary intake of contaminants equal to the mean
56 concentration in prey across all the sites studied. The ‘Worst Case’ scenario assumes a
57 juvenile bird (which has a lower ratio of body weight to food intake rate and hence a higher
58 PPC/PNEC) feeding exclusively at the most contaminated site in each estuary.

59

60 For each of these scenarios, the uncertainty in predicted PPC/PNEC value was determined by
61 Monte Carlo analysis after assigning uncertainties to each model input parameter based on
62 evaluation of empirical data.

63

64 *Selection of contaminants to be modelled*

65 An initial screening exercise was carried out to determine which contaminants to focus on in
66 subsequent modelling. This was carried out by calculating the Predicted Environmental
67 Concentration (PEC) and the Predicted No Effect Concentration (PNEC) in birds for each
68 contaminant. The PEC in this case was the predicted concentration of the contaminant in the
69 prey of the birds and is in this paper termed the PPC. The ratio of the PPC to the PNEC was
70 calculated as:

71

$$72 \quad \frac{PPC}{PNEC} \quad (1)$$

73

74 where values of this ratio above 1 imply a toxic risk. A key prey item, ragworms (*Nereis*
75 *diversicolor*), were sampled from 12 sites in Poole Harbour and 13 sites in the Severn Estuary
76 (Environment Agency, unpubl. res.). It was assumed (for the purposes of the initial screening

77 exercise only) that contaminant concentrations in *Nereis diversicolor* were representative of
78 those in the range of different prey items in each estuary, though in the full uncertainty
79 analysis below, other prey types (earthworms, molluscs and crustaceans) were also
80 considered. Estimates of PPC/PNEC were made for each of the organic and inorganic
81 contaminants measured in *Nereis*. The results of this screening exercise are presented in the
82 Supplementary Material (Tables S1 and S2). Seven compounds (all metals or semi-metals)
83 had maximum PPC/PNEC ratios ≥ 1 : zinc (Zn), lead (Pb), mercury (Hg), selenium (Se), iron
84 (Fe), arsenic (As), and chromium (Cr) for at least one of the sites. Fe was not determined in
85 the Severn Estuary and Se was not determined in Poole Harbour. The source toxicity data
86 used in calculating the screening PPC/PNEC ratios were then examined in detail to determine
87 if they were experimentally sound (if they fulfilled the criteria set out in the *Toxicity Data*
88 Section below) and if the endpoints were ecologically relevant. Using these criteria, only Pb
89 and Hg were selected for subsequent detailed modelling.

90

91 **Model input data**

92

93 *Bird distribution and diet*

94 Bird habitat use and feeding behaviour were estimated using a combination of a foraging
95 model which accounts for the different utilisation of feeding sites within an estuary (Stillman
96 et al., 2005; Durell et al., 2006), the Wetland Bird Survey (WeBS) data and other literature
97 data (Goss-Custard et al., 1988; Worrall, 1984). The proportion of different prey types taken
98 by the birds and their associated uncertainty estimates are shown in Table 1. Earthworms
99 comprise a significant part of the diet for some shorebird species, but in these estuaries dunlin
100 do not consume significant proportions of earthworms in their diet. In Poole Harbour, dunlin
101 have not been observed to eat earthworms (Durell et al., 2006), the major proportion of the

102 diet of adult dunlin being marine worms, the rest being made up of molluscs and crustaceans.
103 In the Severn Estuary, earthworms are estimated to form less than 10% of their diet. Juvenile
104 dunlin (Table 1) take similar food types to adults.

105

106 *Dietary lead and mercury concentrations*

107 The data on Pb and Hg concentrations in *Nereis diversicolor* used in our model comprised
108 not only new measurements (Environment Agency, unpubl. res.) but also data from reviews
109 of contamination in Poole Harbour and the Severn Estuary (Langston et al., 2003b),
110 Supplementary Material, Tables S3-S6). Assumed ranges and estimates of uncertainty in
111 metal concentrations used in the model are summarised in Table 2. For prey items other than
112 *Nereis*, uncertainties in metal concentrations were estimated from data in the reviews, taking
113 account of the known decline in metal contamination over time.

114

115 For the worst-case scenario, it was assumed that the mean concentration of Pb and Hg in
116 *Nereis* was equal to the highest value measured at any of the sites in each harbour with
117 uncertainty being normally distributed with coefficient of variation of 25%. Based on the
118 review of data in Tables S3 – S6, for molluscs and crustaceans it was assumed (for the worst
119 case scenario) that the average concentration at the most contaminated site was 3-10 times
120 higher (Pb, Hg - Poole Harbour; Pb - Severn Estuary) or 1-3 times higher (Hg - Severn
121 Estuary) than the maximum measured value in *Nereis*.

122

123 *Metal concentrations in earthworms (Lumbricus terrestris)*

124 Dunlin in Poole Harbour do not consume earthworms (Durell et al., 2006) and we assumed
125 that this was also true for most dunlin in the Severn Estuary (Table 1). Data on Pb
126 concentrations in earthworms is limited but a study of the Avonmouth smelter found

127 concentrations in worms at an unaffected site distant from the smelter to be 27 mg kg⁻¹ (dw)
128 (Spurgeon, 1994). Concentrations in worms on a control site from a separate study were 4 –
129 12.3 mg kg⁻¹ dw (Morgan and Morgan, 1991).

130 Concentrations of Hg in earthworms measured by (Bull et al., 1977) at a site uninfluenced by
131 industrial activity (range 0.031-0.048 mg kg⁻¹ dw, n = 18) were generally lower than those
132 measured in estuarine biota (see Tables S4 and S6). This suggests that, in contrast to Pb, Hg
133 in earthworms may have little effect on Hg intake in shorebirds.

134

135 *Proportion of dietary mercury as methylmercury*

136 The NOAEL of methylmercury (MeHg) is approximately two orders of magnitude lower than
137 that for inorganic Hg. It is therefore important to estimate the proportion of total Hg in prey
138 items which is in the form of MeHg. Muhaya et al. (1997) determined that the mean
139 proportion of Hg as MeHg in *Nereis* across 13 sites in the Netherlands was approximately
140 18%, but the distribution of values was highly skewed. We therefore log-transformed these
141 data (mean (±SD) log transformed proportion: 1.28 ± 0.22) and used this transformed
142 distribution to generate random values for our Monte-Carlo model. The values were then
143 back-transformed for use in the model.

144

145 *Toxicity data*

146 A literature search was conducted to identify studies from which avian NOAELs could be
147 derived for inorganic and organic Pb and Hg. We used Web of Knowledge (ISI, 2005),
148 Environmental Health Criteria (World Health Organisation, 1989a; World Health
149 Organisation, 1989b; World Health Organisation, 1990; World Health Organisation, 1991),
150 US EPA ECOTOXicology database (U.S. Environmental Protection Agency, 2002), and a
151 number of US EPA reports (Sample et al., 1997; U.S. Environmental Protection Agency,

152 1999; U.S. Environmental Protection Agency, 2005) as reference sources. Where possible,
153 the original papers or reports were assessed, and three criteria were used to decide whether the
154 NOAEL values could be included in our models. These were:

155 (i) effects on reproduction and growth are more likely to affect population densities than
156 lower order effects and in some cases are the integrated response to a range of physiological
157 and biochemical effects. Thus, NOAELs based on reproduction and growth end-points were
158 included but those based on physiological, metabolic, biochemical and other lower level end-
159 points were rejected. This selection procedure also increased the likelihood of finding
160 sufficient toxicity data for our model as there were unlikely to be multiple studies that used
161 exactly the same physiological and biochemical endpoints.

162 (ii) use of only one NOAEL from a study when multiple NOAELs were derived from the
163 same test, thereby avoiding pseudo-replication (when multiple NOAELs were derived in the
164 same study but from different tests, all values were included).

165 (iii) studies in which the highest exposure level was assumed to be the NOAEL were excluded
166 because no effects were observed at any exposure level.

167

168 The value of a NOAEL and Lowest Observed Adverse Effect Levels (LOAELs) is partly
169 determined by the experimental design of the study if, in the case of NOAELs, no effect is
170 observed at the highest dose administered or, in the case of LOAELs, an effect is observed at
171 the lowest dose administered. Using NOAELs derived in such studies may give an over-
172 estimate of the toxicity of a contaminant while using LOAELs may under-estimate the
173 toxicity. NOAELs were used in this study as a precautionary approach in assessing risk to
174 wading birds. Even the studies reporting NOAELs for the effects of Pb and Hg on
175 reproduction and growth are sparse in number. Therefore, we also included studies which
176 reported chronic Lowest Observed Adverse Effect Levels (LOAELs) for appropriate end-

177 points and also investigated the use of LD50 values. Chronic LOAELs were divided by 10
178 and LD50s were divided by 100 to approximate them to chronic NOAELs, following
179 (USACHPPM, 2000).

180
181 The ranges in NOAEL used in our models are summarised in Table 3, and the individual data
182 are presented in Table S7 in the Supplementary Material: this table also gives information on
183 the species on which the tests were conducted. For Pb, we found only four studies that met
184 our selection criteria for NOAELs. There are few avian lethality tests for inorganic Pb and,
185 for those test that have been done, LC50 values typically exceed the highest experimental
186 dose (≥ 5000 mg Pb/kg food). Although we found two avian LD50 values for tetraethyl lead,
187 there appear to be large differences in toxicity between tetraethyl Pb and Pb salts and so we
188 did not use the data for tetraethyl Pb in our model. For Hg, we found five values (two for
189 inorganic Hg, three for Me-Hg) of chronic NOAELs. Seven further NOAELs (six for MeHg,
190 one for inorganic Hg) were derived from LD50 values. For MeHg, there are LD50 values for
191 Hg for six species of bird (multiple values for most species). We calculated a geometric mean
192 LD_{50} for each species, then, divided these figures by 100 to convert them to chronic
193 NOAELs. The range of NOAELs derived in this way was 0.195 to 0.378 mg kg⁻¹ day⁻¹, at
194 least one order of magnitude higher than experimentally-derived chronic NOAELs for methyl
195 mercury dicyandiamide based on reproductive end-points.

196

197 **Modelling**

198 The PPC/PNEC approach was used for the more detailed modelling of Hg and Pb impacts.

199 The PPC was predicted using:

200

$$201 \quad PPC = \sum_i f_i C_i \quad (2)$$

202

203 where f_i is the fraction of the birds' diet composed of prey item i and C_i is the concentration
204 ($\text{mg kg}^{-1} \text{ dw}$) of the metal in prey item i .

205

206 The PNEC was estimated using

207

$$208 \quad \text{PNEC} = \frac{\text{NOAEL}(\text{mg/kg BW/day}) \times \text{BW (kg)}}{\text{FIR (kg DW/day)}} \quad (3)$$

209

210 where NOAEL is the no observable adverse effect level, BW is the bird body weight and FIR
211 is the average daily food intake rate. PPC/PNEC ratios are calculated on a dry weight basis. .

212

213 A Monte-Carlo model was programmed in Microsoft Excel using, where appropriate,

214 Microsoft Visual Basic macros. Using the available data, we ran the Monte-Carlo model to

215 estimate ranges in possible PPC/PNEC values. A total of 10 000 random values were

216 generated for each variable. These were based on a normal (or lognormal, as appropriate)

217 distribution about a mean where data were available to determine the mean and uncertainty.

218 When there were insufficient data to estimate probability distributions, a uniform distribution

219 across the range in observed parameter values was assumed. An additional step was

220 introduced into the model for Hg which was to estimate the fraction of total Hg made up by

221 MeHg. A model sensitivity analysis was carried out by first assigning to each of the input

222 parameters its mean value (c.f. Cox et al., 2006). Individual input parameters were then

223 assigned random values within their uncertainty distributions for 10 000 model runs to

224 determine the impact of uncertainty in each input parameter on the predicted PPC/PNEC

225 value.

226

227 The daily food intake rate (FIR) was estimated using empirical relationships between food
228 intake rate and body weight (BW) (Nagy, 2001). For shorebirds, gulls and auks the daily food
229 intake (FIR; DW, kg d⁻¹) is estimated by regression from data for 15 species in (Nagy, 2001)
230 giving:

231

$$232 \text{ FIR} = 0.11 \times (\text{BW})^{0.77} \quad (4)$$

233

234 (n=15, R²=0.86, p < 0.001). The residuals in this model were approximately lognormally
235 distributed with mean (of logged ratios model:measured) 0 and standard deviation (of logged
236 ratios) 0.123. The regression equation and distribution of residuals was used to determine the
237 best estimate and uncertainty in FIR for dunlin.

238

239 **Results**

240

241 The model gives the probability distribution of estimated PPC/PNEC values based on 10 000
242 model runs for each estuary and scenario. An example of the model output for Pb in Poole
243 Harbour ('Average' Scenario) is shown in Figure 2, and for Hg in the Severn Estuary in
244 Figure 3. All of the model outputs were summarised as the median, 5th and 95th percentile
245 values of PPC/PNEC in Poole Harbour and the Severn Estuary (Table 4).

246

247 *Lead*

248 For the 'Average' Scenario, median PPC/PNEC values for Pb were 2.0 and 6.5 for Poole
249 Harbour and the Severn Estuary respectively (Figure 4). The lowest 5 percentile value was
250 less than 1 in both estuaries, but the highest 95 percentile values were 22 and 75 in Poole
251 Harbour and the Severn Estuary respectively. For the 'Worst Case' scenario, median

252 PPC/PNEC values were only slightly higher than for the 'Average' Scenario; however, 95
253 percentile values were significantly higher, ranging up to 121.

254

255 *Mercury*

256 PPC/PNEC estimates for both estuaries are shown in Figure 5. There were sufficient
257 ecotoxicological data to compare the PPC/PNEC ratios for MeHg based either on
258 experimentally-derived NOAELs or on the much higher approximated values calculated as
259 LD50/100 (Table 3). The predicted PPC/PNEC ratios were much higher when based on
260 experimentally derived NOAELs than when based on the LD50/100 (Figure 5). When the
261 PNEC was estimated using the LD50/100, Hg would not be predicted to have any
262 environmental impact on birds in either estuary, since PPC/PNEC values were lower than 1
263 (with a probability of > 95%). In contrast, there is a significant (i.e. >5%) probability that
264 PPC/PNEC values for Hg based on the experimentally derived NOAEL are greater than 1 in
265 both Poole Harbour and the Severn Estuary. Nevertheless, PPC/PNEC values for Hg (18%
266 MeHg, based on NOAEL) are much lower than for Pb in Poole Harbour with the median
267 PPC/PNEC being close to 1 for both 'Average' and 'Worst Case' scenarios.

268

269 **Sensitivity Analysis**

270

271 We have evaluated the sensitivity of the model to uncertainty in different input parameters.
272 Illustrative results of different sensitivity analyses are discussed here.

273

274 There is a very large uncertainty in the NOAEL for Pb; this varies approximately uniformly
275 over a range spanning two orders of magnitude (Figure 6). As illustrated in Figure 6, this
276 uncertainty in NOAEL dominates the uncertainty in the PPC/PNEC ratio for Pb when all

277 other parameters are assigned their mean value. The predicted PPC/PNEC ratio, when only
278 NOAEL varies, spans a similar range to that predicted when all parameters are allowed to
279 vary. When the sensitivity analysis was carried out for other parameters (i.e. other individual
280 parameters varied whilst all other parameters assigned their mean) the variation in the
281 predicted PPC/PNEC was minor (Figure 6).

282

283 The sensitivity analysis for Hg is illustrated in Figure 7. The PPC/PNEC ratio for Hg is
284 predicted with significantly greater certainty than that for Pb with predicted PPC/PNEC
285 values for Hg being within a range of approximately one order of magnitude. The percentage
286 of Hg in the form MeHg is the most important source of uncertainty in the predicted
287 PPC/PNEC ratio, though uncertainty in Hg content of molluscs, FIR and NOAEL also
288 contribute significantly to model uncertainty.

289

290 The outputs of the sensitivity analysis for different estuary scenarios showed very similar
291 patterns to the illustrative examples we have given for Pb and Hg in Figures 6 and 7
292 respectively.

293

294 **Discussion**

295

296 This assessment of two estuaries showed a potential impact of Hg and Pb contamination on
297 shorebird communities. For the Average Scenario, there was estimated to be a greater than
298 50% probability that PEC/PNEC values exceeded 1 for Pb in both estuaries and for Hg in the
299 Severn Estuary (Table 4). There was an approximately 40% probability that PEC/PNEC
300 exceeded 1 for Hg in Poole Harbour. For the “Worst Case” scenario, probabilities of
301 $PEC/PNEC > 1$ were 95% or greater for both metals in the Severn Estuary and 68 and 75%

302 for Hg and Pb (respectively) in Poole Harbour. For Hg, where PNEC was calculated on the
303 basis of LD50/100, PEC/PNEC values were not predicted to exceed 1 in either estuary (Table
304 4).

305

306 The study on two model estuaries for which relatively strong empirical data on shorebird
307 (dunlin) feeding habits and metal concentrations were available demonstrates that intakes of
308 these metals in metal contaminated estuaries are at levels which may have adverse effects on
309 ecologically-relevant endpoints. This conclusion is based on an assessment of the food uptake
310 pathway. We will, however, briefly consider the potential importance of other uptake
311 pathways for these metals.

312

313 *Alternative Uptake Pathways*

314

315 Because the water-prey bioaccumulation factor is high for these metals, the direct ingestion
316 of water by birds is a much less important uptake pathway than the food pathway we have
317 modelled here. It therefore plays no significant role in predictions of PEC and uncertainty in
318 those predictions (Crane et al., 2005).

319

320 Uptake by ingestion of contaminated soil or sediment may occur incidentally (as, for
321 example, soil or sediment attached to food is ingested) or deliberately (some birds, for
322 example, deliberately ingest grit). Ingestion of contaminated soil or sediment is likely to vary
323 significantly depending on the behaviour and diet of a bird. For different species of birds, the
324 USEPA (USEPA, 1993) have estimated values of <2 % to 30% soil or sediment (per unit dry
325 weight) in faeces of different birds. The highest values were observed in sandpipers which
326 feed on mud-dwelling invertebrates.

327

328 Using data for Pb and Hg in sediments in Poole Harbour (taken from the same sites as *Nereis*
329 were sampled; Environment Agency, unpubl. res.), we have estimated the potential uptake
330 via contaminated sediments in comparison with direct uptake from food. The calculation
331 assumed that either 2% of dry matter intake (DMI) is sediment, or 30% of DMI is sediment.
332 This assumption is based on the USEPA (USEPA, 1993) study of sediment in faeces, though
333 this is likely to be somewhat over-estimated since dry mass of excreted food is lower than dry
334 mass of ingested food. For Pb, the amount of ingested metal per day via sediment was in the
335 range $0.01 - 0.15 \text{ mg d}^{-1}$ (for DMI in the range 2-30%) compared to 0.039 mg d^{-1} via food.
336 For Hg, the ingestion rate via sediment was in the range 7.4×10^{-5} to $1.1 \times 10^{-3} \text{ mg d}^{-1}$
337 compared to $1.6 \times 10^{-3} \text{ mg d}^{-1}$ via food. It should be noted, however, that: (1) the upper range
338 of sediment ingestion rate of 30% may be unrealistically high: for sandpipers the range was
339 estimated to be in the range 7.3-30% (USEPA, 1993) and; (2) metals adsorbed to sediments
340 may be less bioavailable than those in prey (Sheppard et al., 1995). It is, however, possible
341 that direct ingestion of sediment could lead to higher PPC/PNEC values than those
342 determined for the food pathway alone, although uncertainties in metal bioavailability and
343 sediment uptake make the role of the sediment pathway difficult to quantify.

344

345

346 *Uncertainty in Model Predictions*

347 It should be noted that model sensitivity analyses, by definition, only give information on the
348 uncertainty encompassed within the defined model. A sensitivity analysis does not
349 necessarily encapsulate all sources of uncertainty (a limitation of all environmental and
350 ecological models). It is possible that due to unknown factors (which may make model
351 parameters vary to a different extent than those assumed in the model) real PPC/PNEC values

352 may be different to the predicted ranges. For example, the NOAEL values used for this study
353 are necessarily estimated from data on laboratory birds of different species than those studied
354 here. Actual NOAELs of the wild species studied here may be significantly different to those
355 used in the model. Thus sensitivity analysis (whilst being a powerful modelling tool) cannot
356 alone determine predictive uncertainty of environmental models.

357

358 *Reducing uncertainty*

359 Further field studies of metal concentrations in prey and (to the extent which it is possible)
360 field assessments of the impact of metals on bird health/populations would be required to
361 further reduce model uncertainty and to improve assessment of that uncertainty (i.e. validate
362 predictions). For Pb, as shown above, the uncertainty in NOAEL is the dominant factor in
363 model sensitivity, so reducing this uncertainty will have a much greater impact than reducing
364 uncertainty in other parameters. For Hg, uncertainty in NOAEL is also important, but the
365 study has also identified uncertainty in Hg content of prey items, FIR, and relative presence
366 of MeHg as being important sources of uncertainty on which future research should be
367 focussed.

368

369 *Overwintering birds*

370

371 In the context of this modelling study, it is important to realise that, for waders that
372 overwinter in Poole Harbour or the Severn Estuary and migrate to breeding grounds
373 elsewhere, exposure to metal contaminants at the time of breeding may be quite different to
374 that experienced during the winter. It is uncertain what, if any, impacts previous overwinter
375 exposure(s) to Pb or Hg may have on subsequent breeding success. Some of the contaminants
376 accumulated over winter may be remobilised. For example, Pb sequestered in bone may be

377 remobilised as bone (and calcium) turnover increases during egg production, or MeHg in fat
378 may be remobilised as energy reserves are depleted during migration, immediately before
379 breeding starts. There are no toxicological studies that we are aware of that specifically
380 investigate the effects of prior exposures to Pb and Hg on subsequent reproduction; exposure
381 typically occurs prior to and/or during the reproductive cycle. Pharmaco-kinetic modelling
382 would therefore be needed to estimate the likely extent of remobilisation of previously
383 accumulated contaminants and how this might supplement the internal dose derived from
384 dietary intake on the breeding grounds

385

386 The other principal way in which metal intake on overwintering grounds could have
387 ecologically significant effects is their potential contribution to direct over-winter mortality
388 or decrease in likelihood of survival during spring migration. There are no suitable toxicity
389 test endpoints to assess whether survival during migration could be affected. Thus, the only
390 available data are for acute toxicity data (LD₅₀/LC₅₀/NOAEL data), which are also sparse for
391 inorganic Pb and Hg in birds. We did not attempt to use acute toxicity endpoints in most of
392 the probabilistic models but had sufficient ecotoxicological data for methyl-mercury to carry
393 out an assessment using a NOAEL for survival. This was derived by dividing the LD₅₀ data
394 by 100. When this endpoint was used, the modelled median PPC/PNEC ratios were all
395 extremely low, the 95th percentile for the worst case scenario being 0.5. Thus, from this
396 limited assessment, there is no evidence that overwinter dietary intake of Pb or Hg poses an
397 acute toxic threat to dunlin on the Severn Estuary or Poole Harbour.

398

399

400

401

402 **Conclusions**

403

404 The Monte-Carlo based model presented here is able to assess the degree of risk posed to
405 birds feeding on important estuarine habitats, and also shows the limitations of such risk
406 assessments, particularly with regard to data quality and availability. This modelling study
407 indicates that internationally important feeding grounds for waders such as Poole Harbour
408 and the Severn Estuary may pose an ecologically-relevant toxic risk to wading birds. It was
409 found that there was a high probability that PPC/PNEC for Pb significantly exceeded 1 in
410 both areas for dunlin. There was also a high probability that PPC/PNEC for Hg significantly
411 exceeded 1 in the Severn Estuary and a significant (>5%) probability that PPC/PNEC
412 exceeded 1 in Poole Harbour.

413

414 The model largely used data sets which would be typically available and necessary for
415 assessing the impacts of contamination of large estuaries, although data describing feeding
416 preferences and foraging patterns for waders are rarely site-specific. Whilst acknowledging
417 the inevitable limitations in using such data sets (which are made up of data from a number of
418 sources), their use gives a realistic estimate of uncertainty in environmental impact
419 assessments. Such an uncertainty based assessment gives important insights into the
420 limitations of real environmental impact assessments.

421

422 Despite much previous work on its ecotoxicological impacts, a major source of uncertainty in
423 predicting PPC/PNEC values for Pb was the large uncertainty in NOAEL values. Generation
424 of further experimental toxicity data for metals in birds is likely to be extremely limited
425 because of the ethical concerns associated with such work, and it is doubtful that there will be
426 significant reduction in the future in the uncertainty associated with these measures. For Hg,

427 the amount of Hg present as MeHg, FIR and prey metal concentrations were also important
428 sources of uncertainty and further studies to improve the precision of measurements of these
429 parameters would reduce some of the uncertainty when estimating the risks of Hg to wading
430 birds.

431

432 Use of lethal toxicity data (LD50/100) was investigated as a method for assessing sub-lethal
433 impacts from Hg. It was found that this method led to a significant under-estimate of the
434 potential impact of Hg contamination, as compared with direct estimation of NOAEL.

435

436 If significant toxic risk is still predicted following appropriate studies to reduce the
437 uncertainty associated with contaminant levels in prey species, field studies to assess
438 contaminant residues and relevant health indices in waterbirds should be undertaken. These
439 should be focussed on high risk sites where inputs of relevant contaminants are ongoing. An
440 approach which makes use of waterbird carcasses (found dead at relevant sites), similar to the
441 UK's Predatory Bird Monitoring Scheme, should be considered, to provide further insight
442 into the significance of the risk predictions made through the modelling work reported here.
443 Application of non-invasive biomarkers to samples which could potentially be collected
444 during routine ringing operations may provide useful supplementary information.

445

446

447

448

449

450

451

452 **ACKNOWLEDGEMENTS**

453

454 The authors would like to thank the Steering Group for this project, namely Jennifer Best
455 (Natural England), Peter Jonas (Environment Agency) and Chris Nikitik (Environment
456 Agency Wales). Thanks are also due to the Environment Agency for provision of data on
457 contaminant residues in *Nereis* in the Severn Estuary and Poole Harbour.

Figure Captions

Figure 1. Map of Severn and Poole Harbour estuaries.

Figure 2. Predicted PPC/PNEC of Pb in dunlin, Poole Harbour: Average Scenario. The histogram shows the frequency of given PPC/PNEC output values out of 10,000 model runs. Percentage cumulative frequency is shown by the grey line using the right-hand vertical axis. The uncertainty is very high (note the logarithmic scale on the X-axis) due primarily to uncertainty in NOAEL (see Sensitivity Analysis section).

Figure 3. Hg in Dunlin, Severn Estuary, assuming mean fraction of MeHg = 18%. The histograms show the frequency of given PPC/PNEC output values out of 10,000 model runs. Percentage cumulative frequency is shown by the grey line using the right-hand vertical axis. Worst case scenario for PNEC based on (a) LD50/100 or (b) NOAEL based on reproductive endpoints. PPC/PNEC is predicted to be significantly greater than 1 based on NOAEL, but less than 1 based on LD50/100.

Figure 4. Median predicted values of PPC/PNEC for lead in dunlin in Poole Harbour and the Severn Estuary. Error bars show the range of 5-95 percentile predicted values.

Figure 5. Median, predicted values of PPC/PNEC for Hg in dunlin where PNEC is based either on an NOAEL or on LD50/100 in (a) Poole Harbour and (b) the Severn Estuary. Error bars show the range of 5-95 percentile predicted values.

Figure 6 Sensitivity analysis: Pb in dunlin, Poole Harbour (Ave. Scenario). The variation of predicted PPC/PNEC is shown given variation in different individual input parameters, and for variation in all parameters. Uncertainty in NOAEL for Pb dominates uncertainty in PPC/PNEC.

Figure 7 Sensitivity analysis: Hg in dunlin, Severn Estuary (Ave. Scenario). Uncertainty in %MeHg in diet, Hg content of molluscs, FIR and NOAEL all contribute significantly to uncertainty in PPC/PNEC

TABLES

Table 1. Percentage of different food types taken by adult (Average Scenario) and juvenile (Worst Case Scenario) dunlin in Poole Harbour and the Severn Estuary.

Poole Harbour	Percentage food type
Marine worms	78 % S.D. 5%
Molluscs	100% minus % of marine worms
Crustaceans	
Earthworms	0
Severn Estuary	
Marine worms	58 % S.D. 10%
Molluscs	100% minus Σ other
Crustaceans	0
Earthworms	0-10%

Table 2. Assumed distributions (mean \pm S.E. or range) of lead and mercury in prey items for the Average Scenario based on measured data for ragworms and from a literature review for other species (see Tables S3-S6).

Prey type	Pb – Poole H. mg/kg DW	Assumed distribution	Pb – Severn Est. mg/kg DW	Assumed distribution
<i>Nereis</i>	0.71 \pm 0.11	Normal	1.51 \pm 0.32	Normal
Molluscs & crustaceans	0.24 – 7.1	Uniform	0.50-15.1	Uniform
Earthworms	4 – 27	Uniform	4 – 27	Uniform
Prey type	Hg – Poole H. mg/kg DW	Assumed distribution	Hg – Severn Est. mg/kg DW	Assumed distribution
<i>Nereis</i>	0.076 \pm 0.0068	Normal	0.48 \pm 0.1	Normal
Molluscs and crustaceans	0.025 – 0.76	Uniform	0.16 – 1.44	Uniform
Earthworms	Insufficient data		Insufficient data	

Table 3. Ranges and assumed probability distributions of NOAEL and LD50/100 values for Pb and Hg (see Table S7 for details of the studies on which these are based).

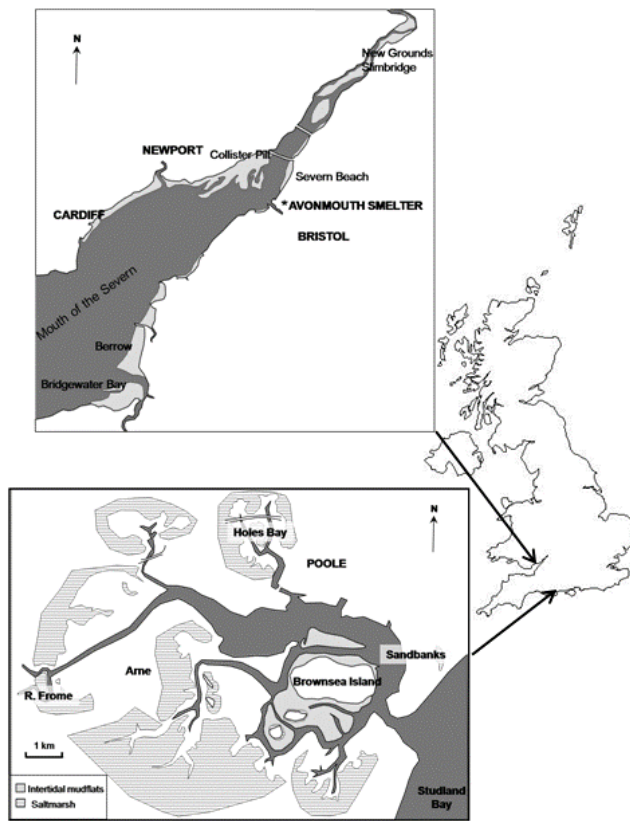

Metal	Endpoint	Range mgMetal/kgBW/d	Assumed probability distribution^a
Pb	NOAEL	0.011-1.6	Uniform distribution of log-transformed values
MeHg	NOAEL	0.0038-0.0108	Uniform
MeHg	LD50/100	0.195-0.378	Uniform
IOM	NOAEL	0.45 – 5.5	Uniform

a. A uniform distribution assumes that the endpoint can take any value between the upper and lower bounds with equal probability.

Table 4. Median, 5 and 95 percentile PEC/PNEC values for dunlin exposed to Pb and Hg in Poole Harbour and the Severn Estuary.

Metal	Scenario	Basis for PNEC	PEC/PNEC 5%	PEC/PNEC 50%	PEC/PNEC 95%
<i>Poole Harbour</i>					
Pb	Average	NOAEL	0.18	1.97	21.8
Hg	Average	NOAEL	0.23	0.79	2.41
Hg	Average	LD50/100	0.0061	0.02	0.055
Pb	Worst Case	NOAEL	0.48	5.62	58.0
Hg	Worst Case	NOAEL	0.45	1.39	4.34
Hg	Worst Case	LD50/100	0.012	0.035	0.10
<i>Severn Estuary</i>					
Pb	Average	NOAEL	0.58	6.45	74.6
Hg	Average	NOAEL	1.01	3.37	10.7
Hg	Average	LD50/100	0.035	0.084	0.19
Pb	Worst Case	NOAEL	1.11	11.7	121
Hg	Worst Case	NOAEL	2.31	6.94	21.9
Hg	Worst Case	LD50/100	0.060	0.18	0.51

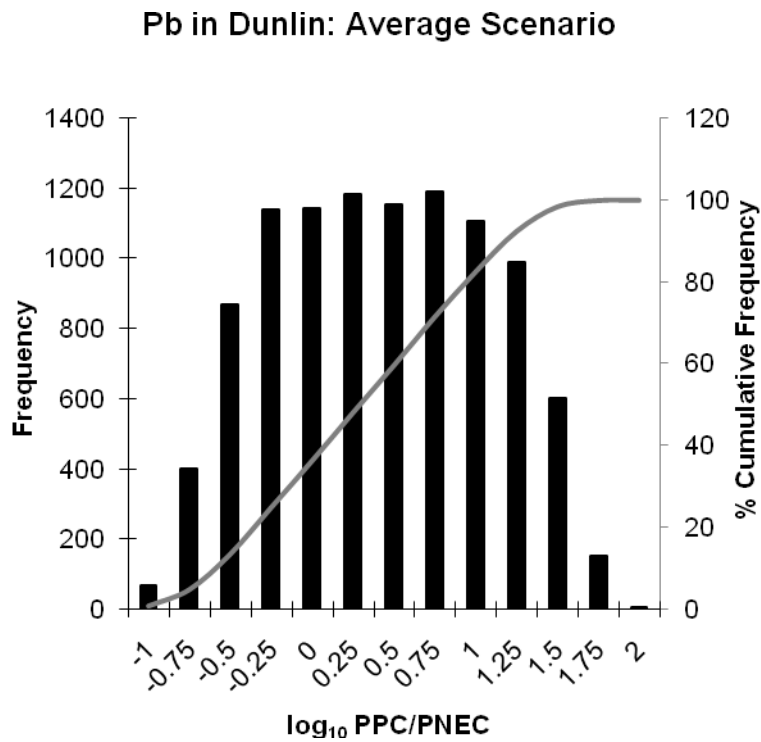

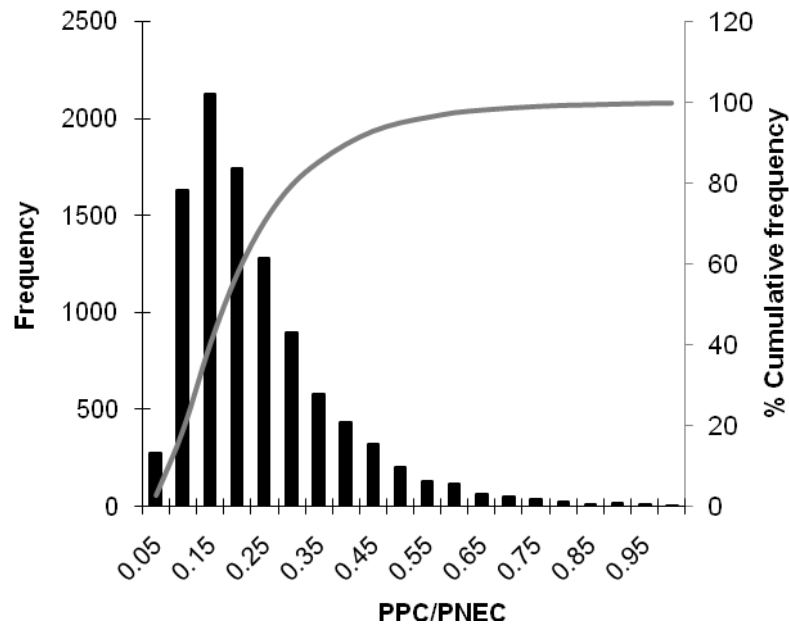

Figure 2. Predicted PPC/PNEC of Pb in dunlin, Poole Harbour: Average Scenario. The histogram shows the frequency of given PPC/PNEC output values out of 10,000 model runs. Percentage cumulative frequency is shown by the grey line using the right-hand vertical axis. The uncertainty is very high (note the logarithmic scale on the X-axis) due primarily to uncertainty in NOAEL (see Sensitivity Analysis section).

(a) Dunlin 18% MeHg Worst Case Scenario using LD50/100

(b) Dunlin 18% MeHg Worst Case Scenario using NOAEL

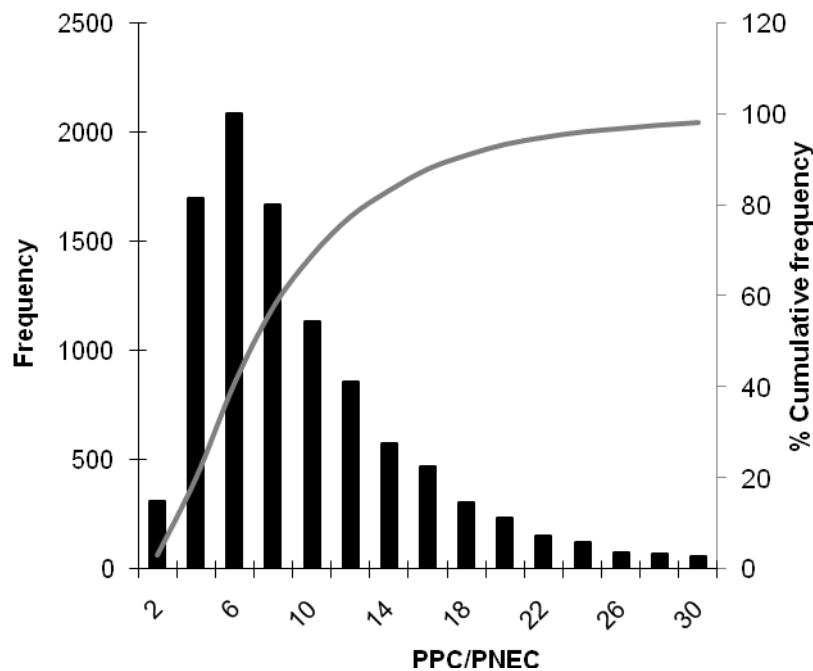

Figure 3. Hg in Dunlin, Severn Estuary, assuming mean fraction of MeHg = 18%. The histograms show the frequency of given PPC/PNEC output values out of 10,000 model runs. Percentage cumulative frequency is shown by the grey line using the right-hand vertical axis. Worst case scenario for PNEC based on (a) LD50/100 or (b) NOAEL based on reproductive endpoints. PPC/PNEC is predicted to be significantly greater than 1 based on NOAEL, but less than 1 based on LD50/100.

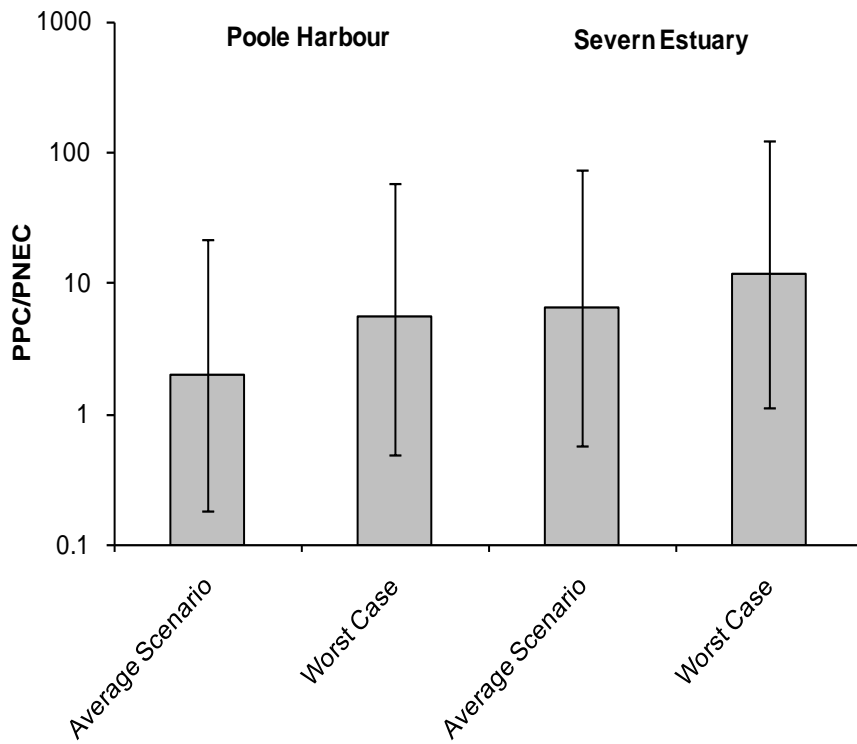

Figure 4. Median predicted values of PPC/PNEC for lead in dunlin in Poole Harbour and the Severn Estuary. Error bars show the range of 5-95 percentile predicted values.

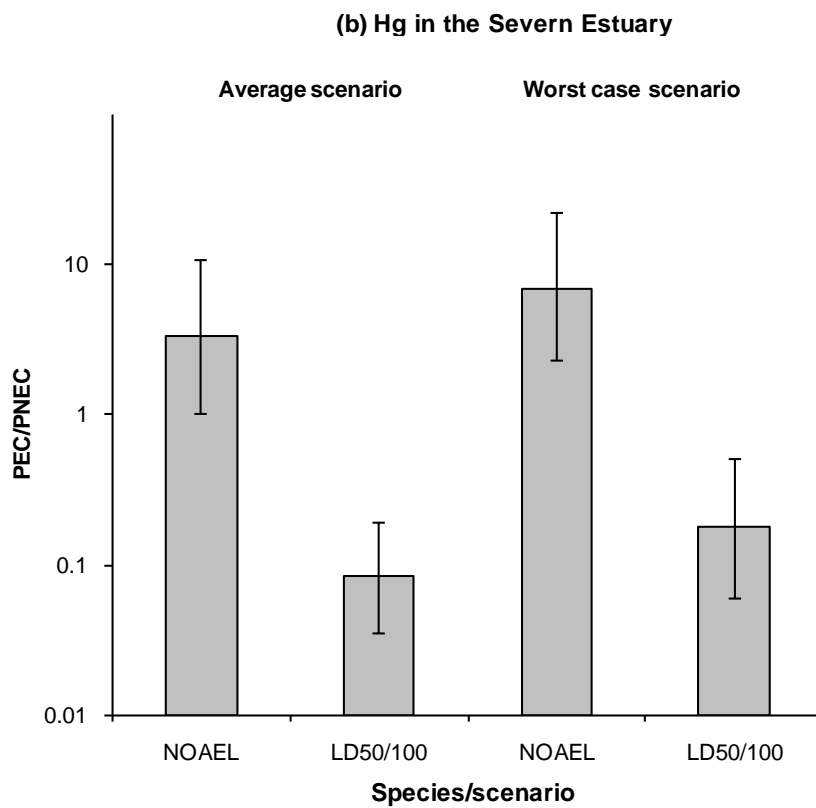

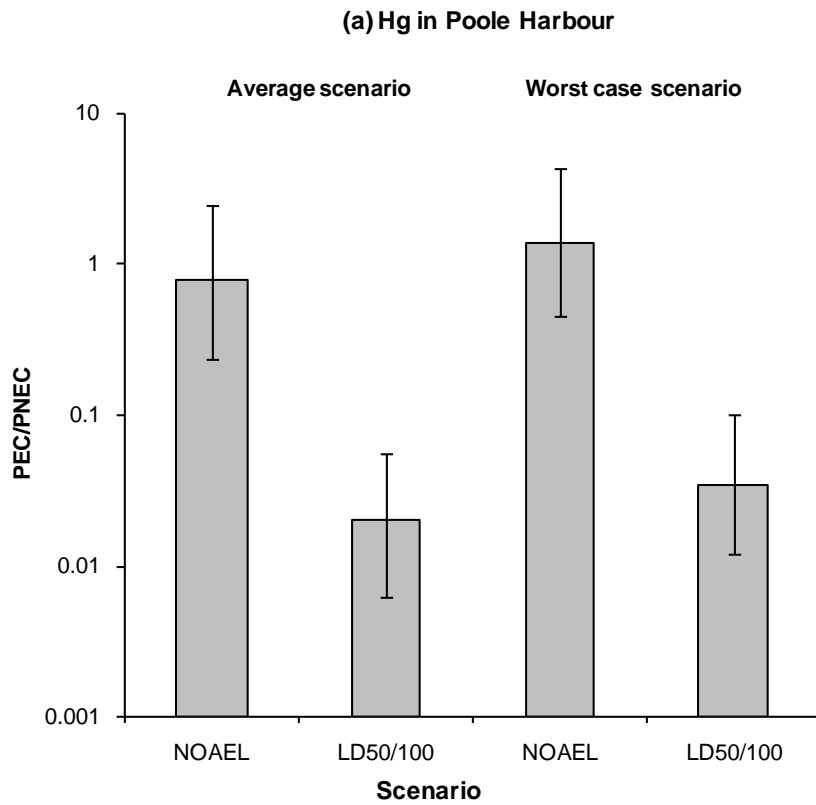

Figure 5. Median, predicted values of PPC/PNEC for Hg in Dunlin where PNEC is based either on an NOAEL or on LD50/100 in (a) Poole Harbour and (b) the Severn Estuary. Error bars show the range of 5-95 percentile predicted values.

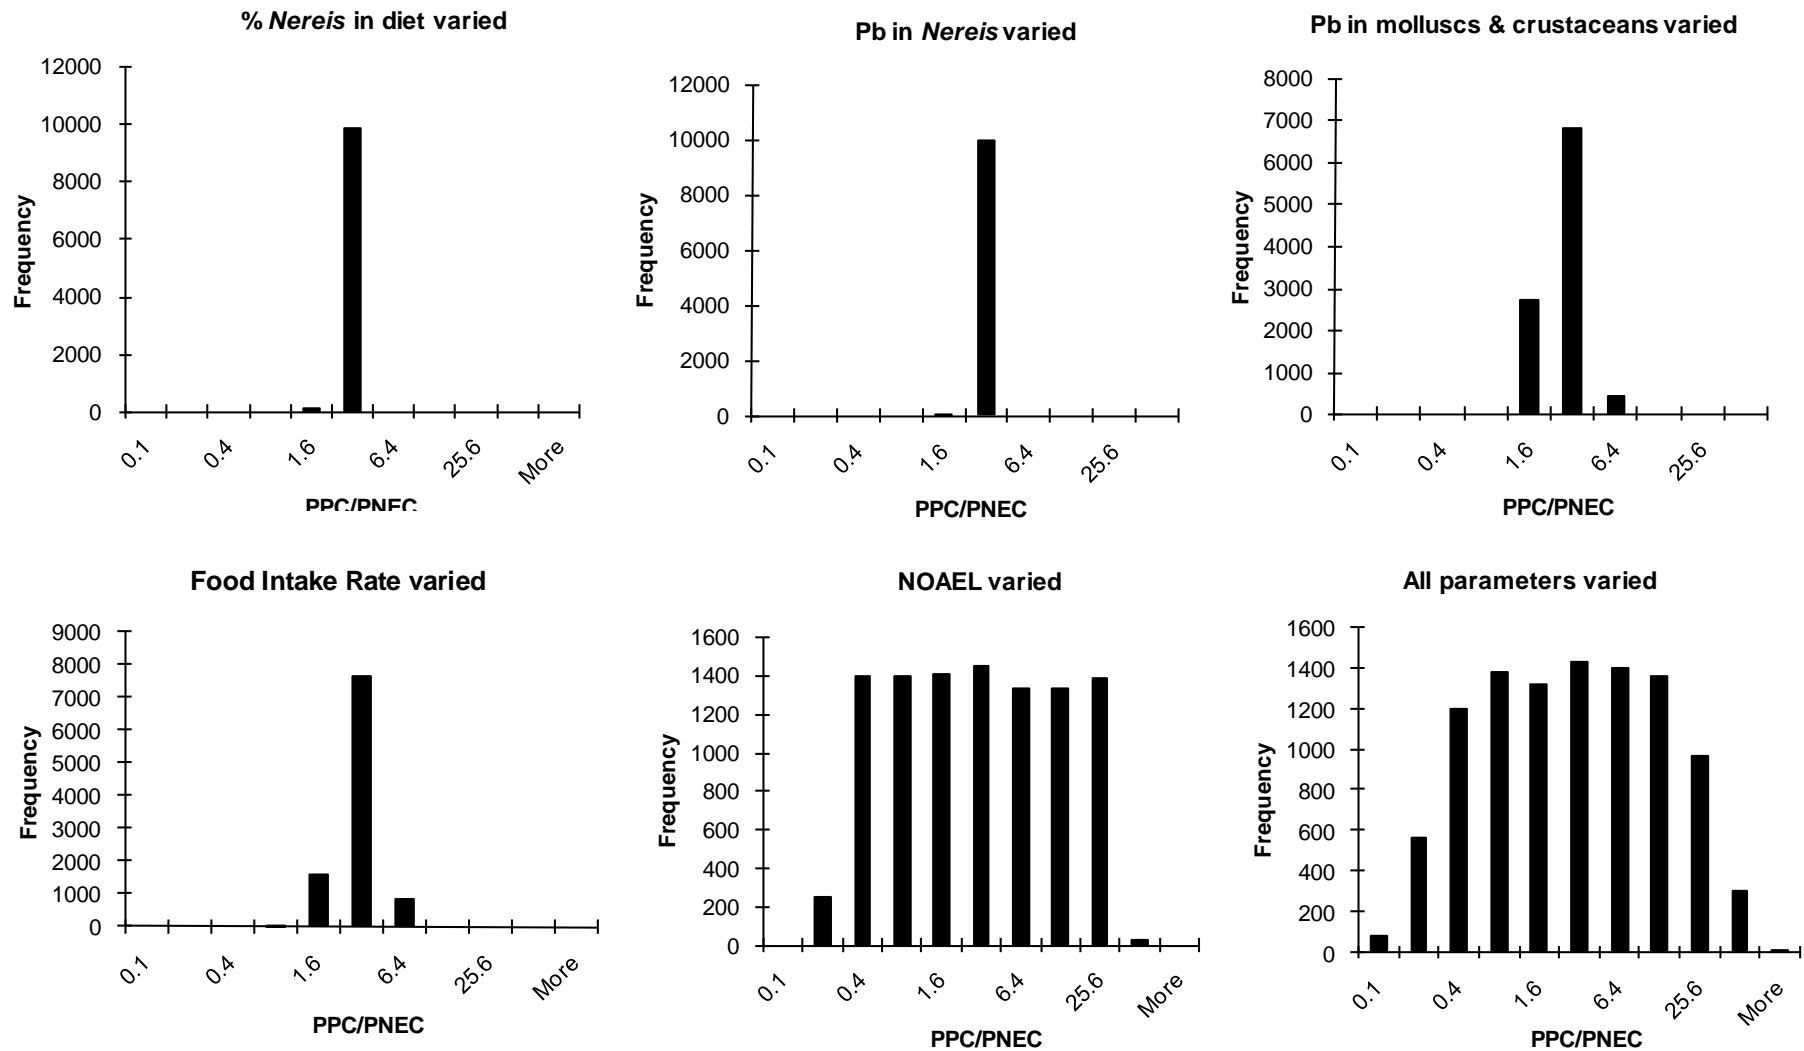

Figure 6 Sensitivity analysis: Pb in Dunlin, Poole Harbour (Ave. Scenario). The histograms show the frequency of given PPC/PNEC output values out of 10,000 model runs. The variation of predicted PPC/PNEC is shown given variation in different individual input parameters, and for variation in all parameters. Uncertainty in NOAEL for Pb dominates uncertainty in PPC/PNEC.

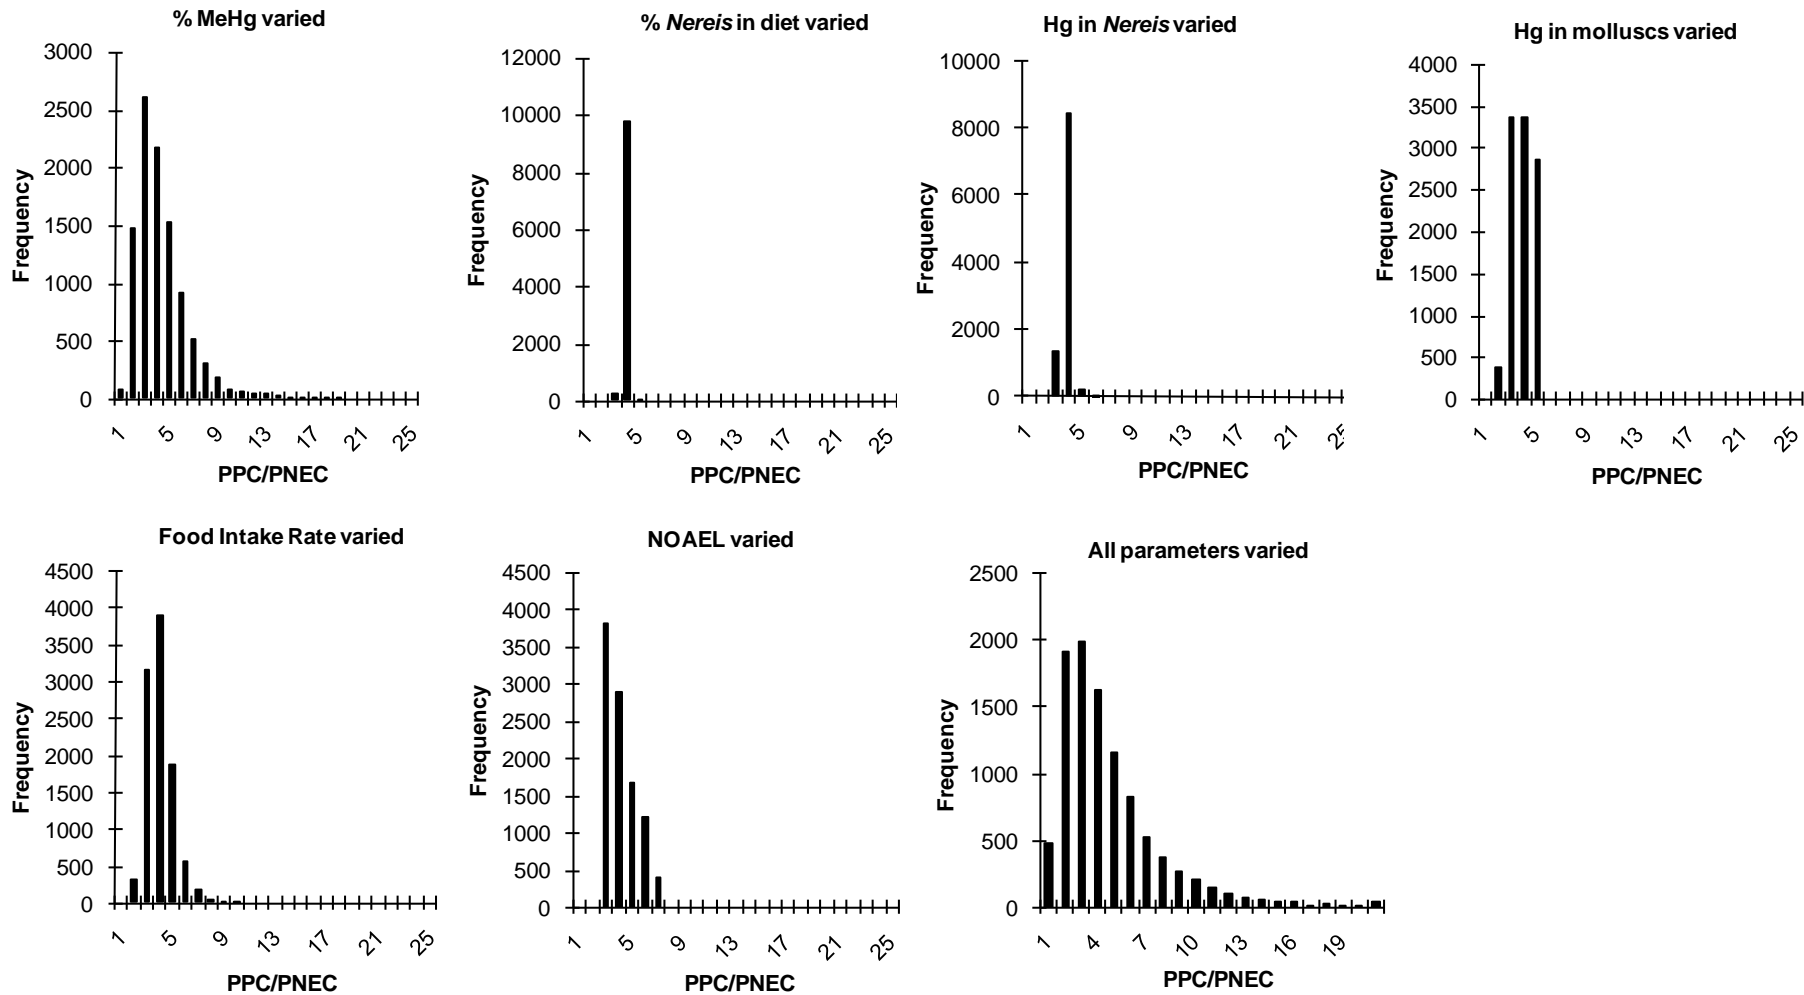

Figure 7 Sensitivity analysis: Hg in Dunlin, Severn Estuary (Ave. Scenario). The histograms show the frequency of given PPC/PNEC output values out of 10,000 model runs. Uncertainty in %MeHg in diet, Hg content of molluscs, FIR and NOAEL all contribute significantly to uncertainty in PPC/PNEC

SUPPLEMENTARY MATERIAL

Table S1. Maximum PPC/PNEC estimated from measurements of contaminants in *Nereis diversicolor* (Environment Agency, unpubl. res.) at 12 sites in Poole Harbour. Contaminants with PPC/PNEC > 1 are highlighted in bold font.

Contaminant	Measured concentration (Range) mg/kg f.w.	NOAEL mg/kgBW/d	Max. PPC/PNEC	Notes
Copper	1.8 - 6.8	47.0 [1]	0.073	
Silver	0.23 – 0.36	>2.3 [2]	<0.12	Used LC50×FIR/1000
Zinc	19 – 44	11 [3]	3.15	
Cadmium	0.011 – 0.36	1.45 [4]	0.08	
Mercury	0.0086 – 0.026	0.0064 [5]	3.1	Assume NOAEL = LOAEL/10 A NOAEL for mercury as organo-metal (methylmercury) was chosen. ^a
Lead	0.11 – 0.36	0.021 [6]	14	
Vanadium	<0.23 – 0.48	1.5 [7]	0.25	
Arsenic	1.5 – 6.0	10.0 [8]	0.47	
Chromium	<0.23 – 0.48	1.0 [3]	0.37	
Manganese	1.0 – 3.6	977 [9]	0.0029	
Iron	67 – 285	1.03 [2]	216	Used LC50×FIR/1000. But NOAEL lower than daily iron requirement.
Nickel	0.41 – 1.5	77.4 [10]	0.015	
PAHs	<0.0005 – 1.1	1.43 [11] Benzo(a)pyrene	All <1	Checked each individual PAH against NOAEC for Benzo(a)pyrene, the most toxic PAH.
Tributyl tin	n.d.	6.8 [12]	-	All measured values were below limit of detection.

a. There is a large disparity between NOAELs for mercuric chloride and methylmercury (0.45 cf. 0.0064 mg/kg bw/d respectively). Using the NOAEL for methyl mercury over estimates the risk. [1] (Mehring et al., 1960) ; [2] (U.S. Environmental Protection Agency, 2002); [3] (Sample et al., 1997); [4] (White and Finley, 1978); [5] (Heinz, 1979); [6] (Edens and Garlich, 1983); [7] (Romoser et al., 1961) [8] (Stanley et al., 1994); [9] (Laskey and Edens, 1985); [10] (Cain and Pafford, 1981); [11] (Hough et al., 1993); [12] (Schlatterer et al., 1993);

Table S2. Maximum PPC/PNEC estimated from measurements of contaminants in *Nereis diversicolor* at 13 sites in the Severn Estuary. The range of organic contaminants that were analysed for was greater than in the *Nereis* collected from Poole Harbour (Table S1).

Contaminant	Measured conc. (Range) mg/kg f.w.	NOAEL mg/kgBW/d	Max. PPC/PNEC	Notes
Copper	7.2 – 20	47.0 [1]	0.33	
Silver	0.25 – 1.6	>2.3 [2]	<0.53	Used LC50*FIR/1000 for NOAEL
Zinc	20 – 55	11 [3]	3.9	
Cadmium	0.024 – 0.25	1.45 [4]	0.13	
Mercury	0.039 – 0.20	0.0064 [5]	22.5	Assume NOAEL = LOAEL/10. Used a NOAEL for mercury as organo-metal (methylmercury). There is a large disparity between NOAELs for mercuric chloride and methylmercury (0.45 cf. 0.0064 mg/kg bw/d respectively).
Lead	0.18 – 0.53	0.021 [6]	34.2	
Arsenic	1.4 – 4.9	10.0 [7]	0.38	
Chromium	0.20 – 1.3	1.0 [3]	1.0	
Nickel	0.32 – 1.3	77.4 [8]	0.013	
Selenium	1.2 – 3.1	0.5 [9]	4.9	Assume NOAEL = LOAEL/10
PAHs	< 0.0005 – 0.8	1.43 [10] (Benzo(a)pyrene)	All <1	Checked each individual PAH against NOAEL for Benzo(a)pyrene, the most toxic PAH.
PCBs	< 0.0001 – 0.0086	0.18 [11] (Arochlor 1254)	Sum <1	Checked sum of PCBs vs NOAEL for Arochlor 1254.
Tributyl tin	n.d. ^b	6.8 [12]	-	All measurements below L.O.D. ^b
a,b,d,g-hexachlorocyclohexane	n.d.			All measurements were below L.O.D.
Aldrin, Dieldrin, Endrin, Isodrin	n.d.			All measurements were below L.O.D.
op-DDT, pp-DDT	n.d.			All measurements were below L.O.D.
pp-DDE	< 0.001 – 0.0012			LC50 = 825 mg/kg. Max 1.19 µg/kg in prey. Only 2 out of 13 samples above L.O.D. ²
pp-TDE	<0.001 – 0.0032			1 out of 13 samples above L.O.D. Measured value 3.2 µg kg ⁻¹ f.w. LD50 = 386 mg kg ⁻¹ BW acute dose.
Hexachlorobutadiene, Hexachlorobenzene	n.d.			All measurements were below L.O.D.

a. n.d. – not detected; b. L.O.D – limit of detection in chemical analysis

<i>Ostrea edulis</i> Native oyster	0.49	0.16	(Langston, 2003a). Data from 1983.
<i>Crassostrea gigas</i> Portuguese oyster		0.26	(Langston, 2003a). Data from 1983.

a. converted to DW basis using a FW/DW ratio of 7 for bivalves.

Table S5. Pb in various biota in comparison with *Nereis*, Severn Estuary

Pb mg kg⁻¹ DW	Avonmouth	Severn Estuary	Notes
<i>Nereis (Hediste) diversicolor</i> Ragworm	0.55-2.3 ^a Mean: 1.51 SE: 0.32		EA supplied data, 2004 range for Severn Estuary
	44.9	11.4; 17.0	(Ferns and Anderson, 1997), samples from 1979/80
	3.56		(Langston et al., 2003b). Mean over 25 year period
<i>Scrobicularia plana</i> Peppery furrow shell	43.5		(Langston et al., 2003b). Mean over 25 yr period.
<i>Mytilus edulis</i> Common mussel		10.0	Environment Agency, unpul. res. 2001-05
<i>Macoma balthica</i> Baltic tellin	40.6	19.5 – 27.5	(Ferns and Anderson, 1997). Samples from 1979/80.
<i>Nephtys hombergi</i> Catworm	91.9		(Ferns and Anderson, 1997). Samples from 1979/80.
<i>Hydrobia ulva</i> Laver spire shell	44.5		(Ferns and Anderson, 1997). Samples from 1979/80.

a. converted to DW basis using a FW/DW ratio of 4.4 for *Nereis*.

Table S6. Hg in various biota in comparison with *Nereis*, Severn Estuary

Hg mg kg⁻¹ DW	Severn Estuary	Notes
<i>Nereis (Hediste) diversicolor</i> Ragworm	0.08 – 0.89 ^a 1.42	This study, range for Severn Estuary (Langston et al., 2003b). Mean over 25 yr period.
<i>Scrobicularia plana</i> Peppery furrow shell	0.64	(Langston et al., 2003b). Mean over 25 yr period.
<i>Mytilus edulis</i> Common mussel	0.61 0.5	(Langston et al., 2003b). Date not known. Environment Agency, unpubl. res., 2001-05

a. converted to DW basis using a FW/DW ratio of 4.4 for *Nereis*.

Table S7. Summary of avian no observed adverse effect levels (NOAELs) for selected contaminants that were included in the probabilistic risk assessment

Metal	Form	Species	Exposure Duration (d)	Critical Endpoint	NOAEL (mg/kg BW/day)	Reference
Pb	Lead acetate	Chicken (<i>Gallus domesticus</i>)	28	Egg Production	1.63	(Edens and Garlich, 1983)
	Lead acetate	Japanese quail (<i>Coturnix c. japonica</i>)	84	Progeny Counts	0.019 ^a	(Edens and Garlich, 1983)
	Lead acetate	Japanese quail (<i>Coturnix c. japonica</i>)	35	Egg Production	0.194	(Edens and Garlich, 1983)
	Lead acetate	Japanese quail (<i>Coturnix c. japonica</i>)	84	Egg Production	0.011 ^a	(Edens et al., 1976)
Hg (inorganic)	Mercury sulphate	White leghorn hen (<i>Gallus domesticus</i>)	21	Egg hatchability	5.5	(Scott, 1977)
	Mercuric chloride	Japanese quail (<i>Coturnix c. japonica</i>)	140	Egg Production	0.45	(Hill and Shaffner, 1976)
	Mercuric chloride	Japanese quail (<i>Coturnix c. japonica</i>)	N/A	Mortality	0.30 ^b	(Hill and Soares, 1984)
Hg (organic)	Methyl mercury chloride	Great Egret (<i>Ardea albus</i>)	91	Growth	0.0038	(Spalding et al., 2000)
	Methyl mercury chloride	Great Egret (<i>Ardea albus</i>)	91	Growth	0.0108	(Spalding et al., 2000)
	Methyl mercury dicyandiamide	Mallard (<i>Anas platyrhynchos</i>)	>365	Egg and Duckling Production	0.0064 ^a	(Heinz, 1979)
	Methyl mercury dicyandiamide	Mallard (<i>Anas platyrhynchos</i>)	N/A	Mortality	0.289 ^b	(Hudson et al., 1984)
	Methyl mercury	Bobwhite quail (<i>Colinus virginianus</i>)	N/A	Mortality	0.239 ^b	(Hudson et al., 1984)
	Methyl mercury	Japanese quail (<i>Coturnix c. japonica</i>)	N/A	Mortality	0.195 ^b	(Hill and Soares, 1984; Hudson et al., 1984)
	Methyl mercury	Fulvous whistling duck (<i>Dendrocygna bicolor</i>)	N/A	Mortality	0.378 ^b	(Hudson et al., 1984)
	Methyl mercury dicyandiamide	House sparrow (<i>Passer domesticus</i>)	N/A	Mortality	0.219 ^b	(Hudson et al., 1984)
	Methyl mercury dicyandiamide	Pheasant (<i>Phasianus colchicus</i>)	N/A	Mortality	0.253 ^b	(Hudson et al., 1984)

a. values based on a LOAEL divided by a factor of 10; b. values based on a LD50 value divided by a factor of 100. N/A indicates that duration of exposure is not applicable as single oral dose was used.
